

## SAMPLE QUESTIONS (CHAPTER 2)

### Section 2.1:

(17) Find the solution of the given initial value problem.

$$y' - 4y = e^{4t}, \quad y(0) = 2$$

---

$$p(t) = -4 \quad \mu(t) = e^{\int p(t) dt} = e^{-4t}$$

Multiplying the equation with  $\mu(t)$ ,

$$e^{-4t} \cdot y' - 4e^{-4t} y = 1.$$

$$(y \cdot e^{-4t})' = 1, \text{ integrating both sides,}$$

$$y(t) \cdot e^{-4t} = t + c, \quad c \in \mathbb{R}$$

$$y(t) = t \cdot e^{4t} + c \cdot e^{4t}$$

$$y(0) = 0 + c = 2, \text{ so we have}$$

the solution of the initial value problem,

$$\boxed{y(t) = (t+2) e^{4t}}$$

③ Find the value of  $y_0$  for which the solution of the initial value problem

$$y' - y = 1 + 3 \sin t, \quad y(0) = y_0$$

remains finite as  $t \rightarrow \infty$ .

---

Clearly,  $\mu(t) = e^{-t}$

$$(y \cdot e^{-t})' = e^{-t} + 3 e^{-t} \sin t, \text{ integrating,}$$

$$y \cdot e^{-t} = -e^{-t} + 3 \int e^{-t} \sin t \, dt$$

We use integration by parts twice to calculate the integral,

$$(*) \quad \int e^{-t} \sin t \, dt = -e^{-t} \sin t + \int e^{-t} \cos t \, dt$$

$$u = \sin t \quad dv = e^{-t} dt$$

$$du = \cos t \, dt \quad v = -e^{-t}$$

$$(**) \quad \int e^{-t} \cos t \, dt = -e^{-t} \cos t - \int e^{-t} \sin t \, dt$$

$$u = \cos t \quad dv = e^{-t} dt$$

$$du = -\sin t \, dt \quad v = -e^{-t}$$

Substituting (\*\*) in (\*), we get

$$\int e^{-t} \sin t = -e^{-t} \frac{(\cos t + \sin t)}{2} + c, \quad c \in \mathbb{R}$$

$$y(t) \cdot e^{-t} = -\frac{e^{-t}}{2} - 3e^{-t} \frac{(\cos t + \sin t)}{2} + d, \quad d \in \mathbb{R}$$

$$y(t) = -1 - \frac{3}{2}(\cos t + \sin t) + d \cdot e^t$$

Placing  $t=0$ ,

$$y(0) = -1 - \frac{3}{2} + d = y_0$$

$$d = y_0 + 5/2$$

Here is our unique solution to the initial value problem

$$y(t) = -1 - \frac{3}{2}(\cos t + \sin t) + (y_0 + 5/2)e^t,$$

as  $t \rightarrow \infty$ ,  $\cos t$  &  $\sin t$  remain bounded, but  $e^t$  diverge to positive infinity. So if we want finite values, we need to eliminate this term, i.e.,

choose  $\boxed{y_0 = -5/2}$ .

## Section 2.2:

⑥ Solve the given differential equation.  $xy' = (1-y^2)^{1/2}$

First, we notice that the equation is separable.

$$(1-y^2)^{-1/2} dy = 1/x dx, \text{ integrating both sides,}$$

$$\arcsin y = \ln x + c, \quad c \in \mathbb{R}$$

So that  $y(x) = \sin(\ln x + c), \quad c \in \mathbb{R}$

①⑨  $\sin 2x dx + \cos 3y dy = 0$  ,  $y(\pi/2) = \pi/3$

---

$\cos 3y dy = -\sin 2x dx$  , the equation is separable,  
integrating both sides,

$$\frac{\sin 3y}{3} = \frac{\cos 2x}{2} + C, \quad C \in \mathbb{R}$$

Using the initial condition,

$$\frac{\sin \pi}{3} = \frac{\cos \pi}{2} + C \Rightarrow C = \frac{1}{2}$$

$$\sin 3y = \frac{3}{2} \cos 2x + \frac{3}{2}$$

$$y(x) = \frac{\arcsin \left( \frac{3}{2} (\cos 2x + 1) \right)}{3}$$

②⑨ Solve the equation

$$\frac{dy}{dx} = \frac{ay+b}{cy+d},$$

where  $a, b, c, d$  are constants.

---

See that we have separability,

$$\frac{cy+d}{ay+b} dy = 1 \cdot dx$$

$$\left( \frac{cy}{ay+b} + \frac{d}{ay+b} \right) dy = 1 dx, \text{ integrating both sides,}$$

$$\frac{c}{a^2} \cdot (ay - b \cdot \ln(ay+b)) + \frac{d}{a} \ln(ay+b) = x + r, \quad r \in \mathbb{R}$$

Hence we have the implicit form of the solution.

### Section 2.4:

- (15) Solve the given initial value problem and determine how the interval in which the solution exists depends on the initial value  $y_0$ .

$$y' + y^3 = 0, \quad y(0) = y_0$$

\_\_\_\_\_

$$\frac{dy}{dx} = -y^3$$

$$-y^{-3} dy = 1 \cdot dx$$

$$\frac{1}{2} y^{-2} = x + c, \quad c \in \mathbb{R}$$

$$\frac{1}{2x+d} = y^2, \quad d \in \mathbb{R},$$

Putting the initial condition,  $d = \frac{1}{y_0^2}$ , moreover

$$y(x) = \frac{y_0}{\sqrt{2y_0^2 x + 1}}, \text{ and it exists as long as}$$
$$2y_0^2 x + 1 > 0$$

$$2y_0^2 x > -1$$

If  $y_0 = 0 \Rightarrow$  Solution exists for all  $x \in \mathbb{R}$ . (It's  $y(x) = 0$ )

If  $y_0 \neq 0 \Rightarrow$  Solution exists for all  $x > \frac{-1}{2y_0^2}$

(27) Bernoulli Equations:  $y' + p(t)y = q(t)y^n$ ,  $n \in \mathbb{N}$

(a) Solve Bernoulli's equation when  $n=0$ ; when  $n=1$ .

---

$$n=0 \Rightarrow y' + p(t)y = q(t), \text{ i.e., usual linear } 1^{\text{st}} \text{ order O.D.E.}$$

$$n=1 \Rightarrow y' + (p(t) - q(t))y = 0, \text{ i.e., usual linear } 1^{\text{st}} \text{ order O.D.E.}$$

(b) Show that if  $n \neq 0, 1$ , then the substitution  $v = y^{1-n}$  reduces Bernoulli's equation to a linear equation. (Leibniz, 1696)

---

$$v = y^{1-n} \Rightarrow v' = (1-n) \cdot y^{-n} \cdot y' \Rightarrow y' = \frac{v' \cdot y^n}{1-n}$$

$$v = y^{1-n} \Rightarrow y = v \cdot y^n$$

Substituting, we have

$$y' + p(t)y = q(t)y^n$$

$$\frac{v' y^n}{(1-n)} + p(t) \cdot v \cdot y^n = q(t) \cdot y^n, \text{ or, equivalently,}$$

$v' + (1-n) \cdot p(t) \cdot v = (1-n)q(t)$ , a first order linear equation with respect to  $v$ .

30) Solve the Bernoulli equation:

$$y' = \epsilon y - \sigma y^3, \quad \epsilon > 0, \sigma > 0.$$

---

$$y' - \epsilon y = -\sigma y^3, \quad n=3, \text{ so let } v = y^{1-n} = y^{-2}$$

$$v' = -2 \cdot y^{-3} \cdot y' \Rightarrow y' = \frac{-v' y^3}{2} \quad y = v \cdot y^3$$

Substituting,

$$\frac{-v' y^3}{2} - \epsilon v \cdot y^3 = -\sigma y^3, \text{ or, equivalently,}$$

$$v' + 2\epsilon v = 2\sigma, \quad \mu(t) = e^{2\epsilon t}$$

$$(v \cdot e^{2\epsilon t})' = e^{2\epsilon t} 2\sigma, \text{ integrating both sides}$$

$$v \cdot e^{2\epsilon t} = \frac{\sigma}{\epsilon} \cdot e^{2\epsilon t} + c, \quad c \in \mathbb{R}$$

$$v(t) = \frac{\sigma}{\epsilon} + c \cdot e^{-2\epsilon t} \quad \text{Recall that } v = y^{-2}, \text{ i.e.,}$$

$$v(t) = \frac{\sigma \cdot e^{2\epsilon t} + \epsilon \cdot c}{\epsilon \cdot e^{2\epsilon t}} \quad y = \sqrt{1/v}$$

$$\text{So } y(t) = \sqrt{\frac{\epsilon \cdot e^{2\epsilon t}}{\sigma \cdot e^{2\epsilon t} + \epsilon \cdot c}}, \quad \text{where } \epsilon, \sigma > 0, \quad c \in \mathbb{R}.$$

### Section 2.6:

(11) Solve the following equation.

$$(y/x + bx) dx + (\ln x - 2) dy = 0, \quad x > 0$$

$$\text{Let } M(x, y) = y/x + bx \quad N(x, y) = \ln x - 2$$

$$\frac{\partial M}{\partial y} = \frac{1}{x} = \frac{\partial N}{\partial x}, \quad \text{so the equation is exact.}$$

There exists a function  $\Psi(x, y)$  such that  $\frac{\partial \Psi}{\partial x} = M$ ,  $\frac{\partial \Psi}{\partial y} = N$  and  $\Psi = c$ ,  $c \in \mathbb{R}$  gives the solution.

$$\Psi = \int M dx = y \cdot \ln x + 3x^2 + g(y), \quad g \text{ is a fn. of } y.$$

$$\frac{\partial \Psi}{\partial y} = \ln x + g'(y) = N = \ln x - 2 \quad \text{So } g(y) = -2y + d, \quad d \in \mathbb{R}$$

Try

$$\frac{d\mu}{dx} = \frac{(x+2) \cos y - \cos y}{x \cdot \cos y} \mu$$

$\underbrace{\hspace{10em}}_{\frac{x+1}{x}}$

Solve the 1<sup>st</sup> order O.d.e,

$$\mu' - \left(\frac{x+1}{x}\right) \mu = 0, \text{ the integrating factor, } \lambda,$$

$$\lambda = e^{-\int \frac{x+1}{x} dx} = e^{-\int 1 dx - \int \frac{1}{x} dx} = x^{-1} e^{-x} = \frac{1}{x e^x}$$

$$\left( \mu \cdot \frac{1}{x e^x} \right)' = 0 \quad \boxed{\mu(x) = x \cdot e^x} \quad \left( \begin{array}{l} \text{without loss} \\ \text{of generality} \\ \text{choose } c=1 \end{array} \right)$$

Multiplying with  $\mu$ , the equation becomes

$$\underbrace{x(x+2) e^x \sin y dx}_{M(x,y)} + \underbrace{x^2 e^x \cos y dy}_{N(x,y)} = 0$$

$$M_y = (x^2 + 2x) e^x \cos y = N_x = (x^2 e^x + 2x e^x) \cos y$$

Equation is exact now. So there is such  $\psi$ .

$$\psi = \int N dy = x^2 e^x \sin y + g(x), \quad g \text{ a fn. of only } x.$$

$$\psi_x = (x^2 + 2x) e^x \sin y + g'(x) = 0 \Rightarrow g'(x) = 0 \Rightarrow g(x) = c, c \in \mathbb{R}$$

Thus we have the solution given by

Hence we have

$$\Psi(x,y) = y \cdot \ln x + 3x^2 - 2y + d, \quad d \in \mathbb{R}$$

and we have

$$y \cdot \ln x + 3x^2 - 2y = c, \quad c \in \mathbb{R}$$

$$y(\ln x - 2) = c - 3x^2$$

$$\boxed{y(x) = \frac{c - 3x^2}{\ln x - 2}}$$

(22) Solve the following equation.

$$(x+2) \sin y \, dx + x \cdot \cos y \, dy = 0$$

Let  $M(x,y) = (x+2) \sin y$        $N(x,y) = x \cdot \cos y$

$$\frac{\partial M}{\partial y} = (x+2) \cos y \neq \frac{\partial N}{\partial x} = \cos y, \text{ not exact.}$$

We will try to find an integrating factor to make this exact.  
If the integrating factor will depend only on  $x$ , it will satisfy

$$\frac{d\mu}{dx} = \frac{M_y - N_x}{N} \mu,$$

if it will depend only on  $y$ , it will satisfy

$$\frac{d\mu}{dy} = \frac{N_x - M_y}{M} \mu.$$

$$x^2 e^x \sin y = d, \quad d \in \mathbb{R}$$

$$\sin y = d x^{-2} e^{-x}$$

$$y(x) = \arcsin\left(\frac{d}{x^2 e^x}\right), \quad d \in \mathbb{R}$$

is the solution.
